DESCRIPTION

The JW[®]H5123 series are current mode monolithic buck switching regulators. Operating with an input range of 4.5V~65V, the JWH5123 series delivers 3.5A of continuous output current with an integrated high side N-Channel MOSFET. At light loads, the regulator operates in low frequency to maintain high efficiency. Current mode control provides tight load transient response and cycle-by-cycle current limit.

The JWH5123 series guarantees robustness with short-circuit protection, thermal protection, current run-away protection, and input under voltage lockout.

The JWH5123 series is available in DFN4x4-10 package, the JWH5123S and JWH5123P are available in ESOP8 package, which provides a compact solution with minimal external components.

*Company's Logo is Protected, "JW" and "JOULWATT" are Registered
Trademarks of JoulWatt technology Inc.*

FEATURES

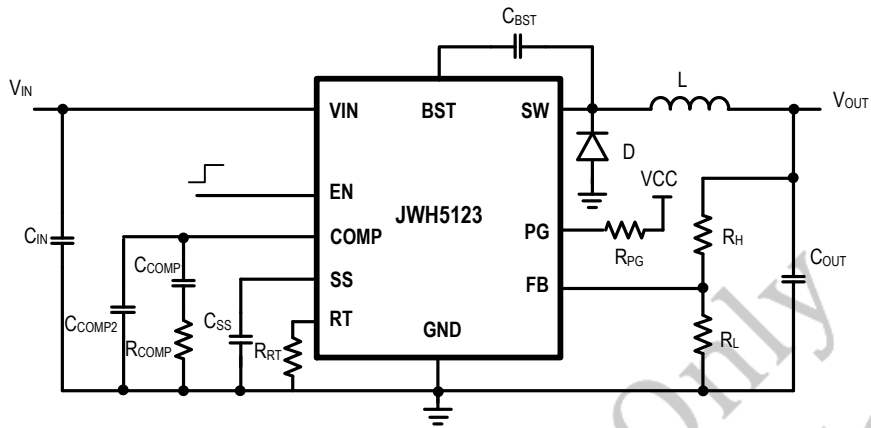

- 4.5V to 65V operating input range
3.5A output current
- 0.8V \pm 1% internal voltage reference (JWH5123)
- 0.75V \pm 1% internal voltage reference (JWH5123S/JWH5123P)
- Adjustable switching frequency
- Power Good Indicator (JWH5123/JWH5123P)
- External Soft-start (JWH5123/ JWH5123S)
- Adjustable UVLO and hysteresis
- Current run-away protection
- Short circuit protection
- Thermal protection
- Available in DFN4x4-10 package (JWH5123)
- Available in ESOP8 package (JWH5123S/ JWH5123P)

APPLICATIONS

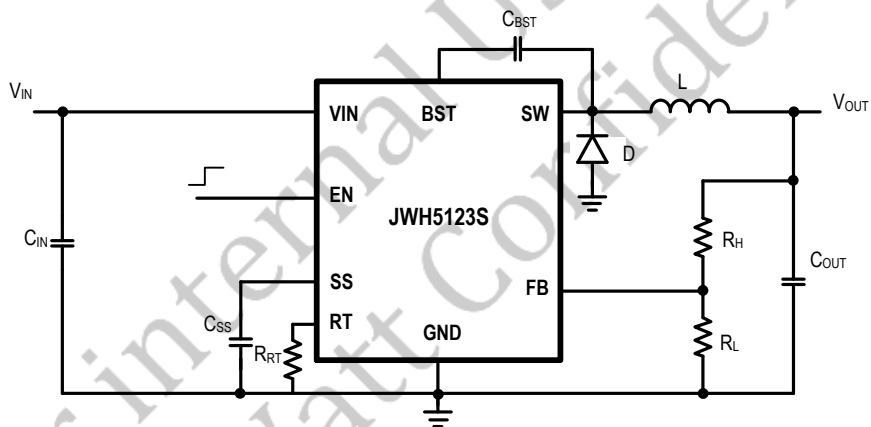

- Industrial Automation and Motor Control
- Vehicle Accessories: GPS Entertainment
- USB Dedicated Charging Ports and Battery Chargers
- 12-V, 24-V and 48-V Industrial, Automotive and Communications Power Systems

TYPICAL APPLICATION

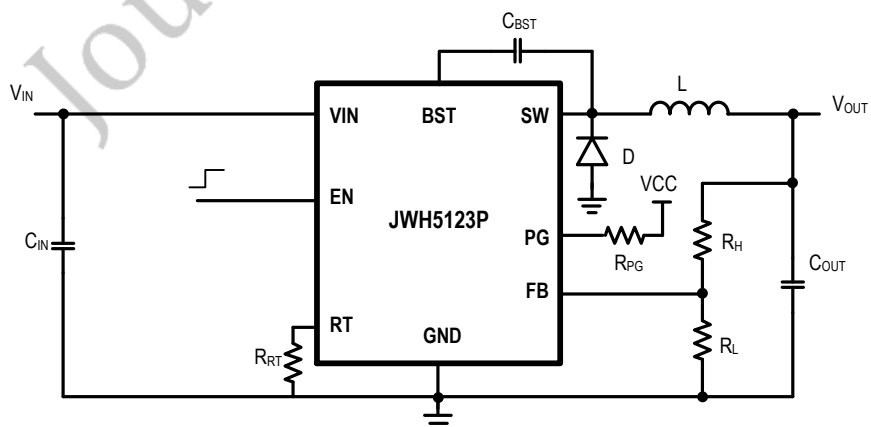

3.5A Step Down Regulators-JWH5123

3.5A Step Down Regulators-JWH5123S

PIN DESCRIPTION

Pin JWH5123	Pin JWH5123S	Pin JWH5123P	Name	Description
1	1	1	BST	Bootstrap pin for top switch.
2	2	2	VIN	Input voltage pin. VIN supplies power to the IC. Connect a 4.5V to 65V supply to VIN and bypass VIN to GND with a suitably large capacitor to eliminate noise on the input to the IC.
3	3	3	EN	Drive EN pin high or floating to turn on the regulator and low to turn off the regulator.
4	6		SS	Soft-start control pin. Leave floating for internal soft-start slew rate. Connect to a capacitor to extend soft start time.
5	4	4	RT	Switching frequency program. Connect an external resistor from RT pin to ground to set the switching frequency.
6	5	5	FB	Output feedback pin. FB senses the output voltage and is regulated by the control loop to V_{ref} . Connect a resistive divider at FB.
7			COMP	Error amplifier output and input to the output switch current (PWM) comparator. Connect frequency compensation components to this pin.
8	7	7	GND	Ground.
9	8	8	SW	SW is the switching node that supplies power to the output. Connect the output LC filter from SW to the output load.
10		6	PG	Open drain output for power-good flag. Use a 10kΩ to 100kΩ pull-up resistor to logic rail or other DC voltage no higher than 5V.
			Exposed Pad	GND pin must be electrically connected to the exposed pad on the printed circuit board for proper operation.

FUNCTIONAL DESCRIPTION

The JWH5123 series are asynchronous, current-mode, step-down regulators. It regulates input voltages from 4.5V to 65V down to an output voltage as low as reference voltage, and is capable of supplying up to 3.5A of load current.

Power Switch

N-Channel MOSFET switch is integrated on the JWH5123 series to down convert the input voltage to the regulated output voltage. Since the top MOSFET needs a gate voltage greater than the input voltage, a boost capacitor connected between BST and SW pins is required to drive the gate of the top switch. The boost capacitor is charged by the internal 4.3V rail when SW is low.

Current-Mode Control

The JWH5123 series utilizes fixed frequency, peak current-mode control to regulate the output voltage. The output voltage is measured at the FB pin through a resistive voltage divider and the error is amplified by the internal transconductance error amplifier.

An internal oscillator initiates the turn on of the high side power switch, and the error amplifier output at the COMP pin controls the high side power switch current that when the high side MOSFET switch current reaches the threshold level set by the COMP voltage, the power switch is turned off.

The COMP voltage will increase and decrease as the output current increases and decreases. The device implements current limiting by clamping the COMP voltage to a maximum level. The PFM mode is implemented with a minimum voltage clamp on the COMP.

PFM Mode

The JWH5123 series operate in PFM mode at light load to improve efficiency by reducing switching and gate drive losses.

During PFM mode operation, the JWH5123 series sense and controls peak switch current, not the average load current. Therefore the load current at which the device enters PFM mode is dependent on the output inductor value.

Slope Compensation Output Current

The JWH5123 series add a compensating ramp to the COMP voltage to prevent sub-harmonic oscillations at duty cycles greater than 50%. The peak current limit of the high side switch will constant with duty cycle increases.

Shut-Down Mode

The JWH5123 series shut down when voltage at EN pin is below 0.3V. The entire regulator is off and the supply current consumed by the JWH5123 series drop below 4 μ A.

Enable and Adjustable UVLO Protection

The JWH5123 series are enabled when the VIN pin voltage rises above 4.3V and the EN pin voltage exceeds the enable threshold of 1.22V. The JWH5123 series are disabled when the VIN pin voltage falls below 4.0V or when the EN pin voltage is below 1.07V. The EN pin has an internal pull-up resistor that enables operation of the JWH5123 series when the EN pin floats.

If an application requires a higher VIN under-voltage lockout (UVLO) threshold, use a resistive divider connected between VIN and ground with the central tap connected to EN to

adjust the input voltage UVLO. (Shown in Figure 1). So that when V_{IN} rises to the pre-set value, EN rises above 1.22V to enable the device and when V_{IN} drops below the pre-set value, EN drops below 1.07V to trigger input under voltage lockout protection.

Figure1. Adjustable UVLO

The input voltage UVLO threshold (V_{UVLO}) and hysteresis (V_{UVLO_HYS}) can be calculated by the following equation.

$$V_{UVLO} = \left(V_{EN_TH} - \frac{2.5V}{1.25M\Omega * \frac{R_{UVLO_upper} + R_{UVLO_lower}}{R_{UVLO_upper} * R_{UVLO_lower}} + 1} \right) * \left(R_{UVLO_upper} * \frac{1.25M\Omega + R_{UVLO_lower}}{1.25M\Omega * R_{UVLO_lower}} + 1 \right)$$

$$V_{UVLO_HYS} = \left(R_{UVLO_upper} * \frac{1.25M\Omega + R_{UVLO_lower}}{1.25M\Omega * R_{UVLO_lower}} + 1 \right) * V_{EN_HYS}$$

When $R_{UVLO_lower} \leq 100k\Omega$, V_{UVLO} can be calculated approximately according to the following equation.

$$V_{UVLO} = \frac{R_{UVLO_upper} + R_{UVLO_lower}}{R_{UVLO_lower}} * V_{EN_TH}$$

$$V_{UVLO_HYS} = \frac{R_{UVLO_upper} + R_{UVLO_lower}}{R_{UVLO_lower}} * V_{EN_HYS}$$

where

V_{EN_TH} is enable shutdown threshold (1.22V typ.);

V_{EN_HYS} is enable shutdown hysteresis (150mV typ.);

External Soft-start

(JWH5123/JWH5123S)

Soft-start is designed in JWH5123 and JWH5123S to prevent the converter output voltage from overshooting during startup and short-circuit recovery. An internal current source I_{SS} is designed to charge the external soft-start capacitor (C_{SS}) and generates a soft-start (SS) voltage ramping up from 0V to 3V. When it is less than internal reference voltage (V_{REF} , typ. 0.8V), SS voltage overrides V_{REF} and the error amplifier uses SS voltage as the reference. When SS exceeds V_{REF} , V_{REF} regains control. The soft start time (10% to 90%) T_{SS} can be calculated by the following equation.

$$T_{SS}(ms) = \frac{C_{SS}(nF) * V_{REF}(V) * 0.8}{I_{SS}(uA)}$$

JWH5123 $I_{SS}=1.8uA$; JWH5123S $I_{SS}=2.8uA$

Switching Frequency

The switching frequency of JWH5123 series can be programmed by the resistor R_{RT} from the RT pin and GND pin over a wide range from 100 kHz to 2000 kHz. The RT pin voltage is typically 1.2V and must have a resistor to ground to set the switching frequency. The R_{RT} resistance can be calculated by the following equation for a given switching frequency f_{sw} .

$$R_{RT}(k\Omega) = \frac{92417}{f_{sw}(kHz)} - 23 \text{--- JWH5123}$$

$$R_{RT}(k\Omega) = \frac{48000}{f_{sw}^{1.08}(kHz)} - 5 \text{--- JWH5123S/JWH5123P}$$

To reduce the solution size one would typically set the switching frequency as high as possible, but tradeoffs of the conversion efficiency, maximum input voltage and minimum controllable on time should be considered. The minimum controllable on time is typically 100 ns which limit the maximum operating frequency in applications with high input to output step down ratios.

Power Good

(JWH5123/JWH5123P)

The JWH5123 and JW5123P has power-good (PG) output. When using this function, it is better to start up through Enable. The PG pin is the open drain of a MOSFET. Connect to a voltage source (such as V_{OUT}) through a resistor. When the output voltage becomes within +6% and -7% of the target value, internal comparators detect power good state and the power good signal becomes high. If the feedback voltage goes under -10% or higher +8% of the target value, the power good signal becomes low.

Over Current / Output Short Protection

To protect the converter in overload conditions at higher switching frequencies and input voltages, the JWH5123 series implements a frequency fold-back. The oscillator frequency is divided by 4 as the FB voltage drops from reference voltage to below 0.35V. When the FB voltage rise above 0.4V, the frequency exist fold-back state. The oscillator frequency is divided by 8 as the FB voltage drops to 0.18V. When the FB voltage rise above 0.2V, the frequency exist fold-back state.

When the output voltage is forced low by the shorted load, the inductor current decreases slowly during the switch off time. The frequency fold-back effectively increases the off time by increasing the period of the switching cycle providing more time for the inductor current to ramp down.

The frequency fold-back effectively increases the off time by increasing the period of the switching cycle providing more time for the inductor current to ramp down. The maximum frequency fold-back ratio is 8.

If the power FET current rises above the current limit by 1.5A, the oscillator frequency is divided by 2^X ($X=0, 1, 2...7$) in a minimum detection time.

Once the power FET is turned off by the current limit instead of minimum on time, the frequency exist fold-back state. With a maximum frequency fold-back ratio of 128, there is a maximum frequency at which the inductor current can be controlled by frequency fold-back protection.

Overvoltage Protection

Output overvoltage protection (OVP) is designed in JWH5123 series to minimize voltage overshoot when recovering from output fault conditions or strong unload transients in designs with low output capacitance and the power supply output voltage increase faster than the response of the error amplifier output resulting in an output overshoot.

The OVP feature minimizes output overshoot when using a low value output capacitor by comparing the FB pin voltage to the rising OVP threshold which is nominally 108% of the internal voltage reference. If the FB pin voltage is greater than the rising OVP threshold, the high side MOSFET is immediately disabled to minimize output overshoot. When the FB voltage drops below the falling OVP threshold which is nominally 106% of the internal voltage reference, the high side MOSFET resumes normal operation.

Thermal Protection

When the temperature of the JWH5123 series rises above 170°C, it is forced into thermal shut-down.

Only when core temperature drops below 150°C can the regulator becomes active again.

APPLICATION INFORMATION

Output Voltage Set

The output voltage is determined by the resistor divider connected at the FB pin, and the voltage ratio is:

$$V_{FB} = V_{OUT} * \frac{R_L}{R_L + R_H}$$

where V_{FB} is the feedback voltage and V_{OUT} is the output voltage.

Choose R_H , and then R_L can be calculated by:

$$R_H = R_L * \left(\frac{V_{OUT}}{0.8} - 1 \right) \text{ for JWH5123}$$

$$R_H = R_L * \left(\frac{V_{OUT}}{0.75} - 1 \right) \text{ for JWH5123S/JWH5123P}$$

Input Capacitor

The input capacitor is used to supply the AC input current to the step-down converter and maintain the DC input voltage. Estimate the RMS current in the input capacitor with:

$$I_{CIN} = I_{OUT} * \sqrt{\frac{V_{OUT}}{V_{IN}} * \left(1 - \frac{V_{OUT}}{V_{IN}} \right)}$$

where I_{OUT} is the load current, V_{OUT} is the output voltage, V_{IN} is the input voltage.

The input capacitor can be calculated by the following equation when the input ripple voltage is determined.

$$C_{IN} = \frac{I_{OUT}}{f_{SW} * \Delta V_{IN}} * \frac{V_{OUT}}{V_{IN}} * \left(1 - \frac{V_{OUT}}{V_{IN}} \right)$$

where C_{IN} is the input capacitance value, f_{sw} is the switching frequency, ΔV_{IN} is the input ripple voltage.

The input capacitor can be electrolytic, tantalum or ceramic. To minimizing the potential noise, a small X5R or X7R ceramic capacitor, i.e. 0.1 μ F, should be placed as close to the IC as possible when using electrolytic capacitors.

A 4.7 μ F*3/100V ceramic capacitor is recommended in typical application.

Output Capacitor

The output capacitor is required to maintain the DC output voltage, and the capacitance value determines the output ripple voltage. The output voltage ripple can be calculated by:

$$\Delta V_{OUT} = \frac{V_{OUT}}{f_{SW} * L} * \left(1 - \frac{V_{OUT}}{V_{IN}} \right) * \left(R_{ESR} + \frac{1}{8 * f_{SW} * C_{OUT}} \right)$$

where C_{OUT} is the output capacitance value and R_{ESR} is the equivalent series resistance value of the output capacitor.

The output capacitor can be low ESR electrolytic, tantalum or ceramic, which lower ESR capacitors get lower output ripple voltage. The output capacitors also affect the system stability and transient response, and a 90 μ F ceramic capacitor is recommended in typical application.

Inductor

The inductor is used to supply constant current to the output load, and the value determines the ripple current which affect the efficiency and the output voltage ripple. The ripple current is typically allowed to be 40% of the maximum switch current limit, thus the inductance value can be calculated by:

$$L = \frac{V_{OUT}}{f_{SW} * \Delta I_L} * \left(1 - \frac{V_{OUT}}{V_{IN}} \right)$$

where V_{IN} is the input voltage, V_{OUT} is the output voltage, f_{sw} is the switching frequency, and ΔI_L

is the peak-to-peak inductor ripple current.

External Bootstrap Capacitor

The bootstrap capacitor is required to supply voltage to the top switch driver. A 0.1µF low ESR ceramic capacitor is recommended to be connected to the BST pin and SW pin.

External Diode

The JWH5123 Series requires an external catch diode between the SW pin and GND. The selected diode must have a reverse voltage rating equal to or greater than $V_{IN(max)}$. The peak current rating of the diode must be greater than the maximum inductor current. Schottky diodes are typically a good choice for the catch diode due to their low forward voltage. The lower the forward voltage of the diode, the higher the efficiency of the regulator. Typically, diodes with higher voltage and current ratings have higher forward voltages. A diode with a minimum of 65 V reverse voltage is preferred to allow input voltage transients up to the rated voltage of the JWH5123 Series. The select forward voltage of Schottky Diode must be less than the restriction of forward voltage in Figure 8 at operating temperature range to avoid the IC malfunction.

Figure8. Restriction of Forward Voltage vs. Temperature
For the example design, the PDS5100H Schottky diode is selected for its lower forward voltage and good thermal characteristics

compared to smaller devices. The typical forward voltage of the PDS5100H is 0.67V at 5A.

Compensation Network Design

In order to ensure stable operation while maximizing the dynamic performance, the appropriate loop compensation is important. Generally, follow the steps below to calculate the compensation components:

1. Set up the crossover frequency, f_c . In general, one-twentieth to one-sixth of the switching frequency is recommended to be the crossover frequency.

2. R_{COMP} can be determined by:

$$R_{COMP} = \frac{2\pi * f_c * C_{OUT}}{g_M * g_{CS}} * \frac{R_L + R_H}{R_L} - R_{COMP1}$$

where $g_M=325\mu A/V$, $g_{CS}=18A/V$,
 $R_{COMP1}=5K\Omega$

3. A compensation zero can be placed at or before the dominant pole of buck which is provided by output capacitor and maximum output loading (R_L). Calculate C_{COMP} :

$$C_{COMP} = \frac{C_{OUT} * R_L}{R_{COMP} + R_{COMP1}}$$

4. The compensation pole is set to the frequency at the ESR zero or 1/2 of the operating frequency. Output capacitor and its ESR provide a zero, and optional C_{COMP2} can be used to cancel this zero.

$$C_{COMP2} = \frac{C_{OUT} * R_{ESR}}{R_{COMP}}$$

If 1/2 of the operating frequency is lower than the ESR zero, the compensation pole is set at 1/2 of the operating frequency.

$$C_{COMP2} = \frac{1}{2\pi * \frac{f_{SW}}{2} * R_{COMP}}$$

5. Generally, C_{COMP2} is an optional component used to enhance noise immunity.

PCB Layout Note

For minimum noise problem and best operating performance, the PCB is preferred to following the guidelines as reference.

1. Place the input decoupling capacitor as close to JWH5123 Series (VIN pin and GND pin) as possible to eliminate noise at the input pin. The loop area formed by input capacitor and GND must be minimized.
2. Put the feedback trace as short as possible, and far away from the inductor and noisy power traces like SW node.
3. Keep the switching node SW short to prevent excessive capacitive coupling
4. Make V_{IN} , V_{OUT} and ground bus connections as wide as possible. This reduces any voltage drops on the input or output paths of the converter and maximizes efficiency.
